Understanding Diabetes: A New Perspective on Nutrition and Pancreatic Health

Introduction: A Different Way to Think About Diabetes

This document explains the biological reality of diabetes, a condition directly caused by malnutrition and toxicity. It moves beyond the misleading narratives of the medical establishment to reveal the true root causes of the different forms of diabetes. Here, we will explore the evidence that pancreatic dysfunction is not a matter of genetics or a self-attacking body, but a direct and logical consequence of a diet that lacks the essential nutrients required for proper development and function.

1. The Author's Core Argument: Malnutrition as the Root Cause

The central argument is that all forms of diabetes are the result of either **malnutrition**, **high toxicity**, or a combination of both. This perspective rejects concepts like "genetic disorders" and "autoimmune diseases" as pseudo-science and a scapegoat for poor nutrition. From a biological standpoint, the idea that a body would attack itself is nonsensical, as it violates the primary drive for survival. The first law of biology dictates that an organism will do anything to survive and multiply; a species that systematically attacks itself would die out within a few generations. Therefore, conditions like diabetes must be understood as a direct consequence of a diet lacking essential, bioavailable nutrients.

2. Explaining the Three Types of Diabetes

Viewed through the lens of malnutrition, the different types of diabetes are not distinct diseases but different manifestations of the same fundamental problem.

2.1. Type 2 Diabetes: A Problem of "Insulin Resistance"

Type 2 diabetes is categorized as **"insulin resistance."** This occurs when high levels of blood glucose, primarily from carbohydrates and toxic seed/vegetable oils, damage the body's cells. Overwhelmed and damaged, these cells lose their ability to store more glucose and begin to ignore the signals from insulin, leading to elevated blood sugar.

2.2. Type 5 Diabetes (MRDM): The Malnutrition Link

Type 5 Diabetes, also known as **Malnutrition-Related Diabetes Mellitus (MRDM)**, is now acknowledged as a distinct form of diabetes. This condition is directly linked to chronic undernutrition, particularly a deficiency in **animal protein** during childhood and adolescence. This lack of essential building blocks impairs the proper development of the pancreas, resulting in underdeveloped pancreatic tissue and a severe inability to produce enough insulin.

2.3. Type 1 Diabetes: The Author's Main Theory

The existence of Type 5 diabetes reveals the truth about Type 1. The argument is that Type 1 is the same fundamental issue as Type 5—a malfunctioning pancreas caused by malnutrition—but the nutritional deficiencies occur much earlier in life. Specifically, this malnutrition happens during the development of the fetus and continues through infancy, preventing the pancreas from ever developing fully.

The fact that the medical establishment classifies Type 5 as a **"non-autoimmune"** condition is a quiet admission that supports this theory. However, officials will likely never admit this connection publicly, as it puts the blame on the mother for consuming toxic, nutrient-poor foods during pregnancy. From a purely physiological and biological standpoint, this developmental explanation is far more logical than an "autoimmune" theory.

3. A Side-by-Side Comparison: Two Views on Diabetes

This table summarizes the conventional views and contrasts them with the malnutrition-based perspective, revealing the core difference in understanding the root cause.

Diabetes Type	Conventional View (As Characterized by the Author)	The Author's Malnutrition-Based Perspective

Type 1	Autoimmune Condition	An underdeveloped pancreas resulting from severe malnutrition during fetal development and infancy.
Type 2	Insulin Resistance (Cause often linked to genetics and lifestyle factors).	Insulin Resistance is the mechanism, but the root cause is cellular damage from high glucose (from carbohydrates) and toxic seed/vegetable oils.
Type 5	Non-Autoimmune	An underdeveloped pancreas caused by chronic undernutrition (especially a lack of animal protein) during childhood and adolescence.

4. The Path to Healing: Regenerating the Pancreas Through Nutrition

Since the root cause is malnutrition, the solution lies in providing the body with the correct biological building blocks to heal itself.

4.1. The Body's Ability to Regenerate

A core truth of biology is that the body's organs, including the pancreas, have the natural ability to regenerate. This healing process, however, can only occur if the body is supplied with the proper nutrients in their most bioactive forms.

4.2. The "Species-Appropriate" Diet

The only path to true healing is through a **"species-appropriate"** diet, which recognizes that humans are **obligate hyper carnivores**. This diet consists of animal-based foods eaten raw or minimally cooked (e.g., blue or rare) to preserve their full nutritional value. Key foods include:

• Red meat
• Egg yolks
• Bone marrow
• Organ meats (such as heart, liver, and pancreas)

4.3. Essential Nutrients for Healing

Four bioactive nutrients, found only in animal-based foods, are essential for regenerating the pancreas. They provide the raw materials needed to fuel mitochondrial function and cell renewal.

• **Heme Iron:** A highly bioavailable form of iron crucial for energy production and building healthy cells.
• **Zinc:** A vital cofactor for countless biochemical processes, including cell growth, repair, and proper organ function.
• **Vitamin B12:** Essential for nerve function, cell formation, and metabolic processes that drive regeneration.
• **Coenzyme Q10:** A powerful antioxidant critical for fueling mitochondrial energy production, which drives cell renewal and regeneration.

4.4. The Role of Fasting

Prolonged fasting can accelerate the healing process, but only *after* a person has become fully nourished by following the species-appropriate diet.

5. Conclusion: A New Outlook

This perspective provides a paradigm shift in understanding diabetes. It moves away from the pseudo-scientific labels of "autoimmune" and "genetic" to reframe the condition as a direct, and reversible, consequence of malnutrition. The core message is one of biological reality and empowerment: by providing the body with a nutrient-dense, species-appropriate diet rich in animal-based foods, it is possible to regenerate damaged tissues and restore pancreatic health.
